ABSTRACT

The investigation reported in this thesis is placed within the context of the development objectives of Indonesia with emphasis placed on improving rice production. Evidence is provided to support the view that too much of the development effort to date has been concentrated on improving rice yield and that problems of a slow increase in agricultural production and inefficient farming still exists. Little attention has been paid to studying these problems.

The main purpose of the thesis is to determine the factors which contribute to the 'levelling off' in the rate of increase of yield and the factors affecting farm-resource allocation and efficiency, and farm profits.

A survey of the relevant literature is made. Models for assessing farm efficiency are discussed and the models used for assessing farm efficiency and farm profits are justified. Partial productivity analyses, the Cobb-Douglas production function, the Cobb-Douglas frontier production function, the Cobb-Douglas unit-output-price profit function and factor analysis were used in the study.

The data used in the study were farm level data collected for the Rural Dynamics Study, Agro Economic Survey, East Java on which the author worked. They were collected from three villages in 1978.

Analysis of the results of the partial productivity measures showed that a yield gap between the actual and the potential yield at the farm level existed. The yield gap, particularly for rice, was about 31 per cent and it was rather less on the 'large' farms. Higher yields were found in Regions 1 and 2 which had relatively better agricultural environments, such as irrigation and good extension services. The yields achieved by sharecroppers and owners did not differ statistically. Further, on the basis of an interpretation of the results of the factor analysis, it was found that better agricultural

information is an important variable in relation to the technical efficiency of farming. Thus improved agricultural information and access to it may be an effective means of obtaining greater efficiency.

On the basis of an interpretation of the production function analyses, the input variables, land, labour and current expenses, all play an important role in the variation of rice output. This finding supports that suggested in the literature, that 'small-area' crops are characterized by high production elasticities for land and small land-to-labour ratios.

The technical efficiency of the farms was analysed using the Cobb-Douglas frontier production function based on linear programming procedures. This analysis enabled productivity estimates at the individual farm level. It was found that the mean per cent technical efficiency rating of the sample farms was 67 per cent and the mean per cent economic efficiency rating was 37 per cent. However, there was a positive relationship between technical efficiency rating and economic rating which indicated that both technical and economic efficiencies have a significant effect on the gross revenue from rice. The greater the technical and economic efficiencies, the greater the gross revenue from the rice.

The gains from achieving efficiency in rice production, and the distribution of profits of the sample farms have been analysed. It was found that rice-farm profits per hectare were 143 and 158 thousand rupiahs in the wet and dry seasons, respectively. However, the distribution of profits was markedly unequal as indicated by the Gini coefficients which were 0.465 and 0.348 in the wet and dry seasons, respectively. Implicitly, this finding supports the view that increases in productivity increase farm income but at the same time widen the inequality of the income distribution. In conjunction with this conclusion, it was indicated that the distributions of total farm area and technical and economic efficiency ratings were a significant determinant of the distributions of profits.

On the basis of an interpretation of the results of the profit function analyses, it was found that the output supply of rice was elastic with respect to the price of output; the own-price elasticities of demand for the factors of production were all above unity; and the cross-price elasticities were relatively small for all the inputs, seed, fertilizer and wages. This indicates that, under existing technology, an output subsidy is likely to induce a greater output response than subsidies on inputs. This conclusion is not meant to imply that an output subsidy is the most effective means of support when producer, consumer and Government interests are taken into account.

The policy implications and directions for further research are presented in Chapter 10. From this chapter, it can be seen that the changes in the technical, economic and institutional framework of agriculture in Indonesia are needed. These include: (a) a need for an expanded programme of agricultural research and extension; (b) a need for an improvement in the ability of the local agricultural extension workers to visit and to teach farmers; (c) a need for further similar research on the yield gap using three data sets, the data from experimental treatment, demonstration plots and farm level data; and (d) a need for a multi-disciplinary study of the problems of small or marginal farmers to determine whether or not agricultural aid and labour-intensive strategies will create a more even income distribution among farmers in the rural areas.

Declaration

I certify that:

- I. The substance of this dissertation has not already been submitted for any degree and is not being currently submitted for any other degree;

- II. Any help received in preparing this dissertation and all sources used have been acknowledged herein.

~~E.P.Piyadasa~~

October 1987.

ACKNOWLEDGEMENTS

This study was carried out while I worked as a principal investigator in the Rural Dynamics Study, Agro-Economic Survey, East Java in 1978-79, and while I was a student at the University of New England, Armidale, New South Wales, Australia from 1980 to 1984 under an AUIDP Scholarship offered by the Government of Australia.

I wish to thank the chairman of the Rural Dynamics Study, Agro Economic Survey of Indonesia, Dr. R. Sinaga and the Project Manager of the Rural Dynamics Study in East Java, Mr. Soentoro, M.S., for permission to use the data. I also would like to thank several of my colleagues in the Rural Dynamics Study at Bogor and Malang, and the Department of Socio-Economics, Faculty of Agriculture, Brawijaya University, and also Dr. W.L. Collier of the Agricultural Development Council of Indonesia, who gave substantial suggestions which helped me to construct the problem definition for the study.

To the Government of Australia, particularly to the AUIDP, which has provided the financial support, I am grateful.

I owe a considerable debt to my supervisor, Dr. T.G. MacAulay, of the Department of Agricultural Economics and Business Management, University of New England. Despite heavy pressures of work, he made himself available and patiently encouraged me to complete this thesis. He provided enthusiastic and constructive criticism. To him I owe a profound debt of gratitude.

Professor J.L. Dillon, currently Head of the Department of Agricultural Economics and Business Management and was a former Pro-Vice Chancellor of the University of New England, also supervised this thesis for nearly one year prior to his departure to the Indian Agricultural Research Institute and ICRISAT, India. I owe him more than can be adequately expressed here. His suggestions and encouragement, especially in the genesis of the thesis is greatly appreciated.

My special acknowledgement goes to the Indonesian Government and Brawijaya University, in particular to Drs. Harsono (Rector), Ir. Soemaryo Poespodarsono, M.Agr. (Dean, Faculty of Agriculture) and Professor Dr. Soetono (former Dean, Faculty of Agriculture), for granting me the opportunity to continue my studies in Australia.

My appreciation also goes to Professor J.B. Hardaker, Dr. R.A. Pearce, Dr. K. Parton, Professor W.F. Musgrave, Dr. H. Doran, Mr. G. Connolly, Mr. S. Pandey, Mr. L.W. Sondakh, all staff or postgraduate students in the Department of Agricultural Economics and Business Management, University of New England, for assistance in providing suggestions. Dr. R.R. Piggott and Professor J.R. Anderson gave many helpful comments on the final draft of some chapters, for which I am grateful. Thanks are due to the secretaries of the Department, Mrs. N. Ferris, Miss J. Barden, Mrs. S. Nano and Mrs. S. Lucas.

I also wish to thank to G. Slocombe, V. Fris and L. Balia for assisting me in the computer work. I am also grateful for the patience and dedication of Dr. D. Evans and Mrs. M. Anker who helped edit my English.

Finally, special thanks to my wife, Dina, who assisted me in editing and correcting the draft of the thesis. She and our son Sandhi, have been kind and generous with their time and love.

Although many people have contributed to the completion of the thesis, the results of the research are entirely my responsibility.

NOTE ON DATA AND UNITS EMPLOYED

Unless otherwise stated, the data used in the study were the data of the Rural Dynamics Study, Agro-Economic Survey, which were collected in East Java in the wet season and dry seasons of 1978.

All weights and measures in the study, as far as possible, have been expressed in the International Standard Units. However, financial amounts were given in Indonesian rupiah (Rp) which was approximately Rp 625 per US\$ 1 in 1978.
