

**INCORPORATION OF COSTS OF ADJUSTMENT IN
DEA MODELS:
SELECTION OF OPTIMAL PATHS**

Filadelfo de Mateo Gómez

Chemical Engineer, Universidad Católica de Valparaíso, Chile
Master of Science in Chemical Engineering, University of Houston, TX, USA

A thesis submitted for the degree of Doctor of Philosophy
of
The University of New England
Armidale, NSW, Australia

August, 2003

Declaration

I certify that the substance of this thesis has not already been submitted for any degree and is not currently being submitted for any other degree or qualification.

I certify that any help received in the preparing of this thesis, and all sources used, have been acknowledged in this thesis.

ABSTRACT

This study focuses on the optimisation of the economic objective of firms and on the determination of the optimal paths of adjustments of their inputs. The path of adjustment is the period-to-period sequence of adjustments that change the quantities of the inputs from the initial to the optimal target values. The target quantities of the inputs are optimal in the sense that they optimise the economic objective of the firm. The adjustment of inputs is feasible only if the present value of the costs of adjustments of inputs is no less than the present value of the reduction of the costs of the inputs.

Data Envelopment Analysis (DEA) is used to define the boundary of the technology or the transformation function for the productive process.

The period-to-period sequence of adjustments suggests a dynamic form of DEA. This dynamic form is derived from allowing DEA for a period-to-period change of peers and of their respective weights. The change of peers may be the deletion of a peer, the incorporation of a new peer or both changes simultaneously. A peer may increase, retain or decrease its weight.

The final dynamic DEA model considers time-varying outputs and time-varying technology. The final dynamic model reduces to the standard DEA model when time is not included in implicit or explicit form. A limitation of the model is that the expected or forecasted data are used as observed data.

The model is used in an empirical application to 35 stores of Dijon, a Chilean retailing firm.

ACKNOWLEDGEMENTS

There were two reasons why I became a Doctor of Philosophy student at the University of New England in 1999. The first reason is that the University of New England offers external candidature. Being a senior staff member (Secretary General) at the Universidad Adolfo Ibáñez in Chile, I was not able to undertake full-time candidature for a PhD degree. The second reason is that I learned of the international reputation of the staff in the Centre of Efficiency and Productivity Analysis (CEPA) within the Department of Econometrics at the University of New England.

I would like to acknowledge with gratitude and thanks my supervisors, Dr. George Battese, Dr. Tim Coelli and Dr. Christopher O' Donnell. Tim and Chris continuously steered my research from engineering criteria to key concepts of microeconomics, firm theory and Data Envelopment Analysis. Their technical expertise was a great help and inspiration. My month-long trips to Armidale for consultations with my supervisors during the last four years, have been very profitable and inspirational to me and greatly assisted me in my research.

Unfortunately for the University of New England, CEPA transferred to the University of Queensland in early 2003 after Prasada Rao, Tim Coelli and Chris O' Donnell accepted senior positions at the University of Queensland in 2002. I have appreciated the help that Tim and Chris have given me, even after their resignations from the University of New England.

George Battese agreed to be a co-supervisor during my candidature, despite the fact that his area of expertise in efficiency and productivity analysis is particularly with stochastic frontier production functions. Since his retirement from UNE in August 2002, George has patiently helped me to put this thesis together in a coherent way. He has helped transform my colloquial Texan/Spanish expressions to more formal Australian English.

I would like to thank Professor Prasada Rao and other former staff of CEPA and of the School of Economics for their friendly and receptive attitudes to me during my trips to the University of New England during July in each of the last four years.

I also wish to thank my employer, Universidad Adolfo Ibáñez, for the financial support that made possible this work.

I give thanks to my wife, Carmen Gloria, and to our daughters, Maricarmen and Monserrat, for their permanent support, their warm full understanding, and their unlimited love.
