Declaration

I certify that the substance of this dissertation has not been already submitted for any degree and is not currently being submitted for any other degree.

I certify that, to the best of my knowledge, any help received in preparing this dissertation, and all sources used, have been acknowledged.

Graham Marshall

Date:

Abstract

Benefits of a climate forecasting system based on identification of phases of the Southern Oscillation were valued for a dryland wheat grower in the vicinity of Goondiwindi. In particular the sensitivity of this value to variation in risk attitude and planting conditions was examined.

Recursive stochastic programming was used to model the sequential decision process within which the climate forecasts would be utilised. The model was designed to identify the actions, including within-season tactical responses to climatic events, that would be chosen in the imminent season with and without use of the forecasts. Actions were identified in the event of each of the climate patterns over the period 1894-1991 recurring. The grower was assumed to apply the expected utility criterion in choosing among actions. The actions at planting time related to choices of nitrogen application rate and cultivar and, at either anthesis or grain maturity, to choices of proceeding with or abandoning each wheat activity.

The action sets identified were used to derive probability distributions for monetary outcomes with and without use of the forecasts. The value of the forecasting system was calculated as the maximum fee the grower could afford to pay for its use without utility being lowered relative to its non-use.

The estimated value of the forecasting system was positive in all of the 60 decision environments analysed except for three where it was zero. The estimated value varied considerably according to assumptions made regarding risk attitude and planting conditions. The mean value across the various sets of planting conditions analysed varied between \$3.52 and \$3.83 per hectare available for wheat growing, depending on the assumed risk attitude of the grower. Variation in risk attitude and planting conditions did not exhibit a consistent directional effect on the estimated value of the forecasting system.

Acknowledgements

I am grateful to the following people who helped me to complete the research culminating in this dissertation:

Kevin Parton and Garry Griffith, my supervisors, for their sage advice and diligent editing.

Graeme Hammer and Roger Stone at the Agricultural Production Systems Research Unit, Toowoomba, for inviting me to extend their work valuing the climate forecasting system and for sharing their thoughts and technical expertise with me.

Dean Holzworth at the Agricultural Production Systems Research Unit for running the agronomic simulations using the wheat module of APSIM.

David Woodruff of the Wheat Research Institute, Toowoomba, for discussing with me the effects of frost on wheat yield and quality.

Peter Cox at CSIRO, Toowoomba, for his thoughts concerning various aspects of valuing a climate forecasting system.

Peter Hayman at NSW Agriculture, Tamworth, for a range of discussions which helped me to make sense of the science.

My colleagues in the Department of Agricultural and Resource Economics at the University of New England for their company.

My ex-colleagues in the Economic Services Unit of NSW Agriculture for encouraging me to enrol in this degree, for giving me moral support in doing the coursework and for paying most of my HECS fees.

Nevertheless the shortcomings of this dissertation are my fault alone.
