December 1996

Declaration

I certify that the substance of this thesis has not already been submitted for any degree and is not currently being submitted for any other degree.

I certify that, to the best of my knowledge, any help received in preparing this thesis, and all sources used, have been acknowledged.

A solid black rectangular box redacting the signature of the author.

Sandra Walpole

Acknowledgments

First and foremost, my sincere appreciation goes to my supervisor Associate Professor Jack Sinden for his patient guidance throughout my PhD. Jack was instrumental in initiating this research, and was a great source of inspiration and encouragement.

Thanks must also go to my co-supervisor Dr John Duggin whose assistance during the course of my study have been appreciated.

The financial support of the Land and Water Resources Research and Development Corporation is also gratefully acknowledged.

Many staff from the NSW Department of Land and Water Conservation (formally the Department of Conservation and Land Management) have provided assistance with this study; Noel Flavel, Des Schroder and Jeremy Black deserve particular mention.

Staff from the Armidale GIS Office of the NSW National Parks and Wildlife Service, in particular Harry Hines, Anne Blaxland and Simon Ferrier, provided important support and facilities throughout this study.

My gratitude is particularly extended to the landholders who were able to spare time to be interviewed during very trying climatic times.

Tim Yapp, Glenn Fox, Colin Brown, Dave Godden, Rob Dumsday, David Oram, Doug Cocks, Mike Young and Lisa Lobry de Bruyn provided many useful comments on various parts of this thesis.

While a great number of other people contributed in various ways to this study, I would like to express my gratitude to the following for offering suggestions and comments that enhanced it:

- all the participants (students and staff) of the Graduate Student Workshops of the UNE Department of Agricultural and Resource Economics who attended my seminar presentations;
- various session participants during my presentations of contributed papers to the Australian Agricultural and Resource Economics Society Annual Conferences in Sydney and Melbourne; and
- various journal editors and referees of several submitted articles based on this study.

I owe special appreciation to Caroline Pizzey for providing editorial assistance during the final months of thesis preparation, and to Robyn Hean for ongoing editorial advice during the course of my PhD.

The word processing assistance of Ron Coleman is also much appreciated.

Thanks to Rob, Susie, Mofe, Chris and Lisa for their moral support and friendship during the good and bad times, and to Carrie for keeping an eye on me over the fence. Thanks also to Chris for the use of his car for all those late-night visits to the office.

Thanks to Reg for always being happy to see me.

A very special thanks to all my family for their ongoing interest, patience and support during my academic career.

All remaining shortcomings of this study are the responsibility of the author.

Abstract

This study is concerned with the economic assessment of programs to manage land degradation at a regional, farm and paddock level in New South Wales. It has been undertaken within an interdisciplinary framework by combining economic and environmental factors. The overall objective is to improve information for decision-making relating to the management of land degradation, through the integration of economic and bio-physical information. Despite increased funding support at Federal and State levels and a significant rise in the number of Landcare groups across Australia, land degradation continues to be a serious environmental problem. There is a lack of reliable information at various scales of management on the impact of land degradation on agricultural productivity, and the economic viability of land-management programs. Furthermore, few attempts have been made elsewhere to integrate economic and bio-physical data to provide prescriptive information to improve management decisions.

A method was developed to estimate the effect of land degradation on agricultural production from cross-sectional data. The analysis was conducted by estimating production functions, which include land degradation as a variable of land quality. Data sets were available on agricultural outputs and inputs such as gross value of agricultural production, area of land under agricultural production, labour, fertiliser and chemicals. Together with land-degradation data from a statewide survey of New South Wales (NSW), the relationship between agricultural output and land degradation was analysed at a regional level for NSW. Opportunity costs of forgone agricultural production were determined from these models to provide estimates of benefits from treatment for each of a number of agro-ecological regions. Costs associated with the management and repair of particular land-degradation types were then calculated. These benefits and costs were converted to present values, and benefit-cost ratios (BCRs) were calculated by region and for individual Local Government Areas (LGAs) within each region. The bio-physical and

management factors most influential in changing these BCRs were determined, and BCRs predicted according to these factors.

This method was then adapted to farm and paddock levels for an area near Gunnedah in north-western New South Wales. Personal interviews were conducted with 31 landholders, from which information on inputs and outputs to production for individual properties in a given financial year was gained. Data on a number of management factors were also recorded. Using an overlay of property boundaries on geographic information system (GIS) data, bio-physical information was determined for each farm. These bio-physical attributes included slope, terrain, land use, timber, erosion, soil type and soil-erosion control earthworks. Opportunity costs of forgone agricultural production were determined to provide estimates of benefits from treatment for each farm. The costs associated with the management and repair of soil erosion were then calculated. Having calculated the BCRs for each farm, the bio-physical and management factors that were most influential in changing these values were determined. Predictive modelling was then undertaken in the GIS, allowing the BCRs estimated at the farm level to be extended and interpolated across the study area.

A significant interdisciplinary contribution of this study is the successful integration of economic and bio-physical information. Using predictive modelling techniques in a GIS, economic information in the form of BCRs was integrated with bio-physical attributes, such as slope, soil type and land degradation, allowing the extrapolation and display of this information beyond conventional economic boundaries.

The main findings are as follows. (a) The general method of analysis was successfully applied at the regional, farm and paddock level. (b) Production functions estimated at the three levels of management showed that inputs such as area of land, labour, fertiliser and chemicals had a significant positive influence on agricultural output, and land degradation had a significant negative influence on agricultural output. (c) Benefit-cost ratios calculated at the regional, farm and paddock level indicate there are many profitable opportunities for undertaking management programs to combat or prevent land degradation.

Based on the above findings, recommendations are made for improving expenditure decisions at each of the management levels. At the regional level, the empirical results provide broad indicators of the impact of land degradation and where priorities should be given in terms of funding and management. At the farm and paddock levels, the

continued presence of profitable opportunities for soil-conservation measures suggests that high levels of risk are involved in this type of expenditure and that a risk-averse farmer may choose to invest elsewhere. On the basis of the initial success of methods developed in this project, further research that incorporates economic and bio-physical information in models is recommended.
